## GitLab Inc. — Infrastructure Platforms

Re: Site Reliability Engineer, Infrastructure Platforms — AMER (Remote, US)

Dear Infrastructure Platforms Hiring Team,

I am applying for the Site Reliability Engineer role on Infrastructure Platforms. Most SRE candidates have **consumed** a cloud platform. I **built** one: I spent five years taking **Cloud.mn**, Mongolia's first public cloud, from an empty rack to **300+ enterprise tenants** on OpenStack, KVM and Kubernetes — writing the control-plane services, owning the on-call rotation, and holding a **99.95% availability target** in production.

That work maps closely to what this role asks for. I wrote **net-new infrastructure tooling rather than configuring existing tools**: backend control-plane services built from scratch against the OpenStack Compute, Networking, Identity and Storage APIs, and provisioning automation that turned customer onboarding self-service and cut manual provisioning time by **90%**. At Tech Partners I codified a fragile single-instance production environment into a **multi-AZ AWS platform in reusable Terraform modules**, then built the observability stack underneath it — Prometheus, Grafana, Node Exporter and **Blackbox Exporter probes** wired to symptom-based alerts on ASG lifecycle events, RDS saturation and endpoint health, so we found degradation before customers did rather than waiting for an outage.

I also write the code, not just the pipelines. **MedOrder**, a regulated healthcare platform handling **40,000+ pharmaceutical orders**, is my **Go** service running on Kubernetes with PostgreSQL and Redis — I own it end to end, application and infrastructure. My CI/CD standardization across five products ran on **GitLab CI** and GitHub Actions with OWASP-aligned scanning and rolling deploys, cutting change failure rate by **30%**. And my AWS and hybrid on-prem-to-cloud background lines up directly with the single-tenant side of Infrastructure Platforms as well as the fleet side.

On the toil question, I take it literally. Running **EasySim.mn** solo — no ops team, no downtime budget — I replaced first-line customer support with an **LLM agent** doing RAG over the product knowledge base with custom tools that act on live orders, so that queue stopped consuming engineering time entirely. That same instinct is why the runbooks I wrote at Tech Partners were handed to the operations team: reliability work that stays in one person's head is not finished.

GitLab's way of working suits how I already operate. EasySim was built remotely and asynchronously as a manager-of-one, and every platform I have run has been documented in runbooks first so the next person could operate it without me. I would welcome the chance to discuss where my experience fits best across Production Engineering, Dedicated and Delivery.

Thank you for your time and consideration.

Sincerely,

**Darkhanbayar Erdenebat**
